

Life Expectancy at Age 65

Name	Life Expectancy at Age 65
Short/Other Names	Not applicable
Description	Number of years a person would be expected to live, starting from age 65, if the age- and sex-specific mortality rates for a given reference period were held constant over his or her life span
Interpretation	A higher life expectancy at age 65 is considered an indicator of better overall health of the older population.
HSP Framework Dimension	Health System Outcomes: Improve health status of Canadians
Areas of Need	Not applicable
Geographic Coverage	All provinces/territories
Reporting Level /Disaggregation	International, National, Province/Territory, Region, Neighbourhood Income Quintile

Identifying Information	
Name	Life Expectancy at Age 65
Short/Other Names	Not applicable
Indicator Description and Calculation	
Description	Number of years a person would be expected to live, starting from age 65, if the age- and sex-specific mortality rates for a given reference period were held constant over his or her life span Cumulative number of person-years lived by persons age 65 and older, divided by the number of persons age 65 and older in the initial cohort
Calculation: Description	A period life table approach is used, applying the age- and sex-specific mortality rates for a given reference period to a hypothetical cohort. Life tables are usually constructed separately for men and women because of their different mortality rates.
Calculation: Geographic Assignment	Place of residence
Calculation: Type of Measurement	Average or mean
Calculation: Adjustment Applied	None
Calculation: Method of Adjustment	Not applicable Standard Population: Not applicable
Denominator	Description: Population age 65 in an initial cohort of 100,000 people Description: Cumulative number of person-years lived by persons age 65 and older, for a cohort of 100,000 persons Age- and sex-specific mortality rates corresponding to the reference period are applied to a hypothetical cohort, typically of 100,000. Starting at age 65, the probability of dying at each age or age interval is applied to the number of people surviving to that age or to the beginning of the age interval, respectively.
Numerator	Exclusions: Rates used by Statistics Canada to calculate life expectancy are calculated with data that excludes the following: 1. Births to mothers who are not residents of Canada 2. Births to mothers who are residents of Canada whose province or territory of residence was unknown 3. Deaths of non-residents of Canada 4. Deaths of residents of Canada whose province or territory of residence was unknown 5. Deaths for which age or sex of the decedent was unknown
Background, Interpretation and Benchmarks	
Rationale	Used worldwide, and often in combination with life expectancy at birth, life expectancy at age 65 is understood as a measure of the general health of the older population. By definition, life expectancy is affected by age- and sex-specific mortality rates for the 65 and older population in a particular reference period. Life expectancy measures quantity rather than quality of life.
Interpretation	A higher life expectancy at age 65 is considered an indicator of better overall health of the older population.

Quality Statement

Caveats and This indicator does not provide information on the individual causes of death or on quality of life for the older population.

Limitations The data is based on 2018 health region boundaries. For complete Canada coverage, each northern territory represents a health region.

Trending Issues Due to improvements in methodology and timeliness, the duration of data collection has been shortened compared with previous years. As a result, there may have been fewer deaths captured by the time of the release. The 2017 data is therefore considered preliminary.

Estimates based on 3 years of pooled data are available at the regional level from 2000 to 2002 forward, with the most current data being for 2015 to 2017.

Life expectancy at age 65 does not provide information about the quality of life of the older population. Other measures have been developed using a composite of morbidity and mortality data. For example, health-adjusted life expectancy (HALE) at age 65 is the average number of remaining years that an individual is expected to live in a healthy state (PHAC, 2012).

Comments Indicator results are based on three years of pooled data. The reference point reflects the mid-point of a three-year period.
